

# CS396: Security, Privacy & Society

Fall 2022

Lecture 12: Public-key Cryptography

**Instructor: Abrar Alrumayh**

October 17, 2022

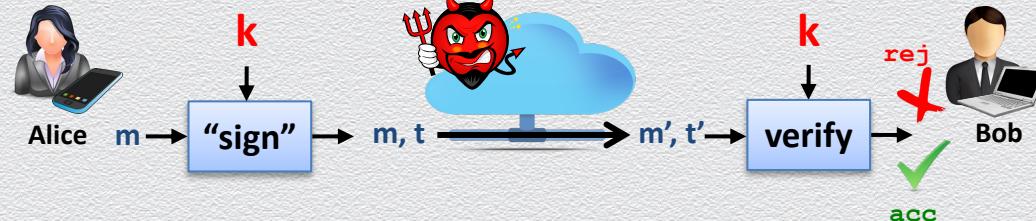

# **Public-key encryption & digital signatures**

# Recall: Principles of modern cryptography

(A) security definitions, **(B) precise assumptions**, (C) formal proofs

For **symmetric-key** message encryption/authentication

- ◆ adversary
  - ◆ types of attacks
- ◆ trusted set-up
  - ◆ secret key is distributed securely
  - ◆ secret key remains secret
- ◆ trust basis
  - ◆ underlying primitives are secure
  - ◆ PRG, PRF, hashing, ...
    - ◆ e.g., block ciphers, AES, SHA-2, etc.

# On “secret key is distributed securely”

Alice & Bob (or 2 individuals) must **securely obtain a shared secret key**

- ◆ “securely obtain”
  - ◆ need of a secure channel
  
- ◆ “shared secret key”
  - ◆ too many keys

**strong assumption** to accept

**challenging problem** to manage

**Public-key cryptography to the rescue...**

# On “secret key is distributed securely”

Alice & Bob (or 2 individuals) must **securely obtain a shared secret key**

- ◆ “securely obtain”  **(A) strong assumption** to accept
  - ◆ requires secure channel for key distribution (chicken & egg situation)
  - ◆ seems impossible for two parties having no prior trust relationship
  - ◆ not easily justifiable to hold a priori
- ◆ “shared secret key”  **(B) challenging problem** to manage
  - ◆ requires too many keys, namely  $O(n^2)$  keys for n parties to communicate
  - ◆ imposes too much risk to protect all such secret keys
  - ◆ entails additional complexities in dynamic settings (e.g., user revocation)

# Alternative approaches?

Need to securely distribute, protect & manage many **session-based** secret keys

- ◆ (A) for secure distribution, just “make another assumption...”
  - ◆ employ “**designated**” **secure channels**
    - ◆ physically protected channel (e.g., meet in a “sound-proof” room)
  - ◆ employ “**trusted**” **party**
    - ◆ entities authorized to distribute keys (e.g., key distribution centers (KDCs))
- ◆ (B) for secure management, just ‘live with it!’

**Public-key cryptography to the rescue...**

# Public-key (or asymmetric) cryptography

disclaimer on names  
private = secret

Goal: devise a cryptosystem where key setup is “more” manageable

Main idea: **user-specific** keys (that come in pairs)

- ◆ user U generates two keys ( $U_{pk}$ ,  $U_{sk}$ )
  - ◆  **$U_{pk}$  is public** – it can safely be known by everyone (even by the adversary)
  - ◆  **$U_{sk}$  is private** – it must remain secret (even from other users)

Usage

- ◆ employ **public** key  $U_{pk}$  for certain “**public**” tasks (performed by **other users**)
- ◆ employ **private** key  $U_{sk}$  for certain “**sensitive/critical**” tasks (performed by **user U**)

Assumption

- ◆ **public-key infrastructure (PKI)**: public keys become **securely** available to users

# From symmetric to asymmetric encryption

## secret-key encryption

- ◆ main limitation
  - ◆ **session-specific** keys

## public-key encryption

- ◆ main flexibility

- ◆ **user-specific** keys

- ◆ messages encrypted by receiver's PK can (only) be decrypted by receiver's SK

# From symmetric to asymmetric message authentication

## secret-key message authentication (or MAC)

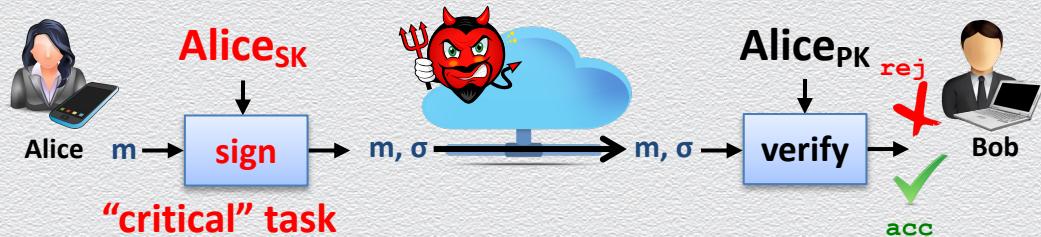

- ◆ main limitation
  - ◆ **session-specific** keys

## public-key message authentication

### (or **digital signatures**)

- ◆ main flexibility
  - ◆ **user-specific** keys

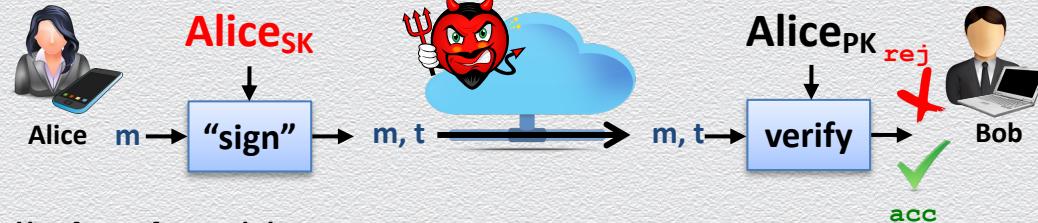

- ◆ (only) messages signed by sender's SK can be verified by sender's PK

# Thus: Principles of modern cryptography

(A) security definitions, **(B) precise assumptions**, (C) formal proofs

For **asymmetric-key** message encryption/authentication

- ◆ adversary
  - ◆ types of attacks
- ◆ trusted set-up
  - ◆ PKI is needed
  - ◆ secret keys remain secret
- ◆ trust basis
  - ◆ underlying primitives are secure
  - ◆ typically, **algebraic** computationally-hard problems
    - ◆ e.g., **discrete log, factoring**, etc.

# General comparison

## Symmetric crypto

- ◆ key management
  - ◆ less scalable & riskier
- ◆ assumptions
  - ◆ secret & authentic communication
  - ◆ secure storage
- ◆ primitives
  - ◆ generic assumptions
  - ◆ more efficiently in practice

## Asymmetric crypto

- ◆ key management
  - ◆ more scalable & simpler
- ◆ assumptions
  - ◆ authenticity (PKI)
  - ◆ secure storage
- ◆ primitives
  - ◆ math assumptions
  - ◆ less efficiently in practice (2-3 o.o.m.)

# Public-key infrastructure (PKI)

A mechanism for securely managing, in a dynamic multi-user setting,  
user-specific public-key pairs (to be used by some public-key cryptosystem)

- ◆ **dynamic, multi-user**
  - ◆ the system is open to anyone; users can join & leave
- ◆ **user-specific public-key pairs**
  - ◆ each user  $U$  in the system is assigned a unique key pair  $(U_{pk}, U_{sk})$
- ◆ **secure management** (e.g., authenticated public keys)
  - ◆ public keys are authenticated: current  $U_{pk}$  of user  $U$  is publicly known to everyone

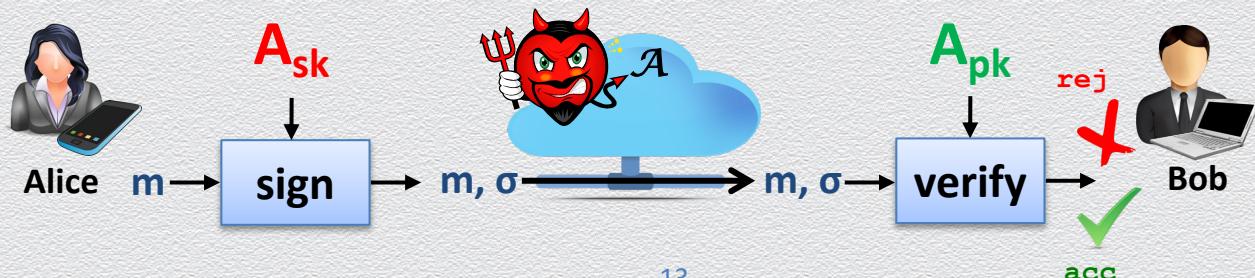

Very challenging to realize

- ◆ currently using **digital certificates**; ongoing research towards a better approach...

# Overall: Public-key encryption & signatures

Assume a trusted set-up

- ◆ public keys are securely available (PKI) & secret keys remain secret

# Secret-key vs. public-key encryption

	<b>Secret Key (Symmetric)</b>	<b>Public Key (Asymmetric)</b>
<b>Number of keys</b>	1	2
<b>Key size (bits)</b>	56–112 (DES), 128–256 (AES)	Unlimited; typically no less than 256; 1000 to 2000 currently considered desirable for most uses
<b>Protection of key</b>	Must be kept secret	One key must be kept secret; the other can be freely exposed
<b>Best uses</b>	Cryptographic workhorse. Secrecy and integrity of data, from single characters to blocks of data, messages and files	Key exchange, authentication, signing
<b>Key distribution</b>	Must be out-of-band	Public key can be used to distribute other keys
<b>Speed</b>	Fast	Slow, typically by a factor of up to 10,000 times slower than symmetric algorithms

# Public-key cryptography: Early history

Proposed by Diffie & Hellman

- ◆ documented in “New Directions in Cryptography” (1976)
- ◆ solution concepts of public-key encryption schemes & digital signatures
- ◆ key-distribution systems
  - ◆ Diffie-Hellman key-agreement protocol
    - ◆ “reduces” symmetric crypto to asymmetric crypto

Public-key encryption was earlier (and independently) proposed by James Ellis

- ◆ classified paper (1970)
- ◆ published by the British Governmental Communications Headquarters (1997)
- ◆ concept of digital signature is still originally due to Diffie & Hellman

# **Public-key certificates**

# How to set up a PKI?

- ◆ How are public keys stored? How to obtain a user's public key?
- ◆ How does Bob know or 'trust' that  $A_{PK}$  is Alice's public key?
- ◆ How  $A_{PK}$  (a bit-string) is securely bound to an entity (user/identity)?

public key:  $A_{PK}$   
secret key:  $A_{SK}$

public key:  $B_{PK}$   
secret key:  $B_{SK}$

# Achieving a PKI...

How can we maintain the invariant that at all times

- ◆ any given **user U** is **assigned** a **unique** public-private key pair; and
  - ◆ any other user known U's **current** public key?
    - ◆ secret keys can be lost, stolen or they should be revoked
- entails binding  
users/identities  
to public keys

Recall

- ◆ PK cryptosystems come with a Gen algorithm which is run by U
  - ◆ on input a security-strength parameter, it outputs a random valid key pair for U
- ◆ public keys can be made publicly available
  - ◆ e.g., sent by email, published on web page, added into a public directory, etc.

# Distribution of public keys

## Public announcement

- ◆ users distribute public keys to recipients or broadcast to community at large

## Publicly available directory

- ◆ can obtain greater security by registering keys with a public directory

Both approaches have problems and are vulnerable to forgeries

# Do you trust your public key?

- ◆ Impostor claims to be a true party
  - ◆ true party has a public and private key
  - ◆ impostor also has a public and private key
- ◆ Impostor sends impostor's own public key to the verifier
  - ◆ says, "This is the true party's public key"
  - ◆ this is the critical step in the deception

# Certificates: Trustable identities & public keys

## Certificate

- ◆ a public key & an identity **bound** together
- ◆ in a document **signed by** a certificate authority

## Certificate authority (CA)

- ◆ an authority that users **trust** to securely bind identity to public keys
  - ◆ CA **verifies identities** before generating certificates for these identities
  - ◆ secure binding via **digital signatures**
    - ◆ **ASSUMPTION:** The authority's PK  $CA_{PK}$  is authentic

# Public-key certificates in practice

Current (imperfect) practice for achieving trustable identities & public keys

- ◆ everybody trusts a Certificate Authority (CA)
  - ◆ everybody knows CA<sub>PK</sub> & trusts that CA knows/protects corresponding secret key CA<sub>SK</sub>
- ◆ a certificate binds identities to public keys in a CA-signed statement
  - ◆ e.g., Alice obtains a signature on the statement “Alice’s public key is 1032xD”
- ◆ users query CA for public keys of intended recipients or signers
  - ◆ e.g., when Bob wants to send an encrypted message to Alice
    - ◆ he first **obtains & verifies** a certificate of Alice’s public key
  - ◆ e.g., when Alice wants to verify the latest software update by Company
    - ◆ she first **obtains & verifies** a certificate of Company’s public key

# Example

a certificate is a public key and an identity bound together and signed by a certificate authority (CA)

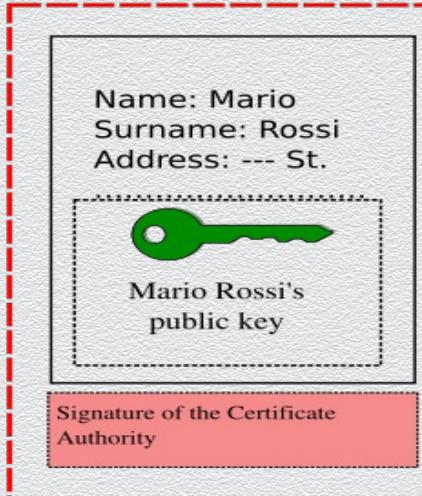

Document containing the public key and identity for Mario Rossi

Certificate Authority's private key

Mario Rossi's Certificate

document signed  
by CA

a certificate authority is an **authority** that users **trust** to accurately verify identities before generating certificates that bind those identities to keys

# Certificate hierarchy

Single CA certifying every public key is impractical

Instead, use trusted **root certificate authorities**

- ◆ root CA signs certificates for intermediate CAs,  
they sign certificates for lower-level CAs, etc.
  - ◆ certificate “**chain of trust**”
    - ◆  $\text{sign}_{\text{SK\_Symantec}}(\text{"Stevens"}, \text{PK}_{\text{Stevens}})$
    - ◆  $\text{sign}_{\text{SK\_Stevens}}(\text{"faculty"}, \text{PK}_{\text{faculty}})$
    - ◆  $\text{sign}_{\text{SK\_faculty}}(\text{"Abrar"}, \text{PK}_{\text{Abrar}})$

# Example 1: Certificate signing & hierarchy

## To create Diana's certificate:

Diana creates and delivers to Edward:

Name: Diana
Position: Division Manager
Public key: 17EF83CA ...

Edward adds:

Name: Diana	hash value 128C4
Position: Division Manager	
Public key: 17EF83CA ...	

Edward signs with his private key:

Name: Diana	hash value 128C4
Position: Division Manager	
Public key: 17EF83CA ...	

Which is Diana's certificate.

## To create Delwyn's certificate:

Delwyn creates and delivers to Diana:

Name: Delwyn
Position: Dept Manager
Public key: 3AB3882C ...

Diana adds:

Name: Delwyn	hash value 48CFA
Position: Dept Manager	
Public key: 3AB3882C ...	

Diana signs with her private key:

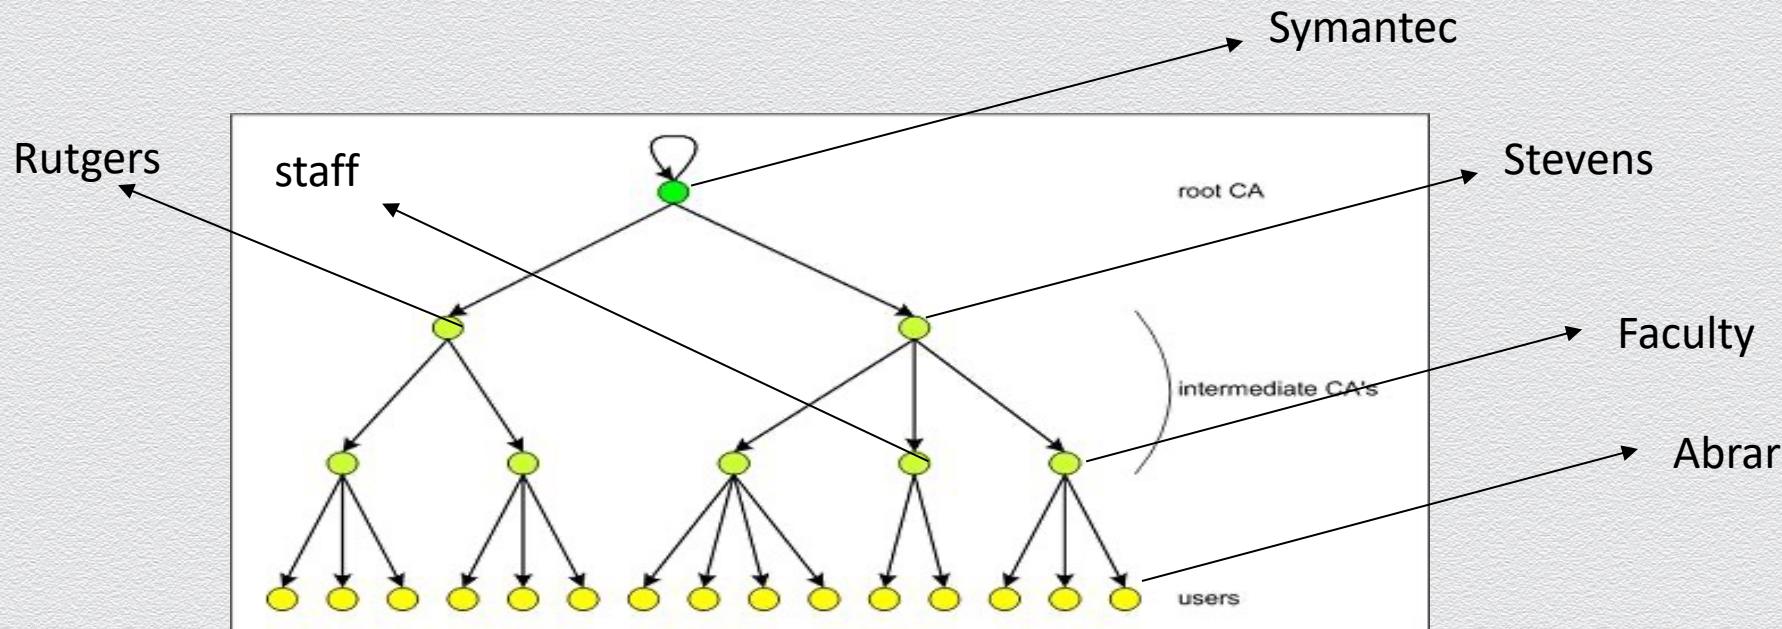

Name: Delwyn	hash value 48CFA
Position: Dept Manager	
Public key: 3AB3882C ...	

And appends her certificate:

Name: Delwyn	hash value 48CFA
Position: Dept Manager	
Public key: 3AB3882C ...	
Name: Diana	hash value 128C4
Position: Division Manager	
Public key: 17EF83CA ...	

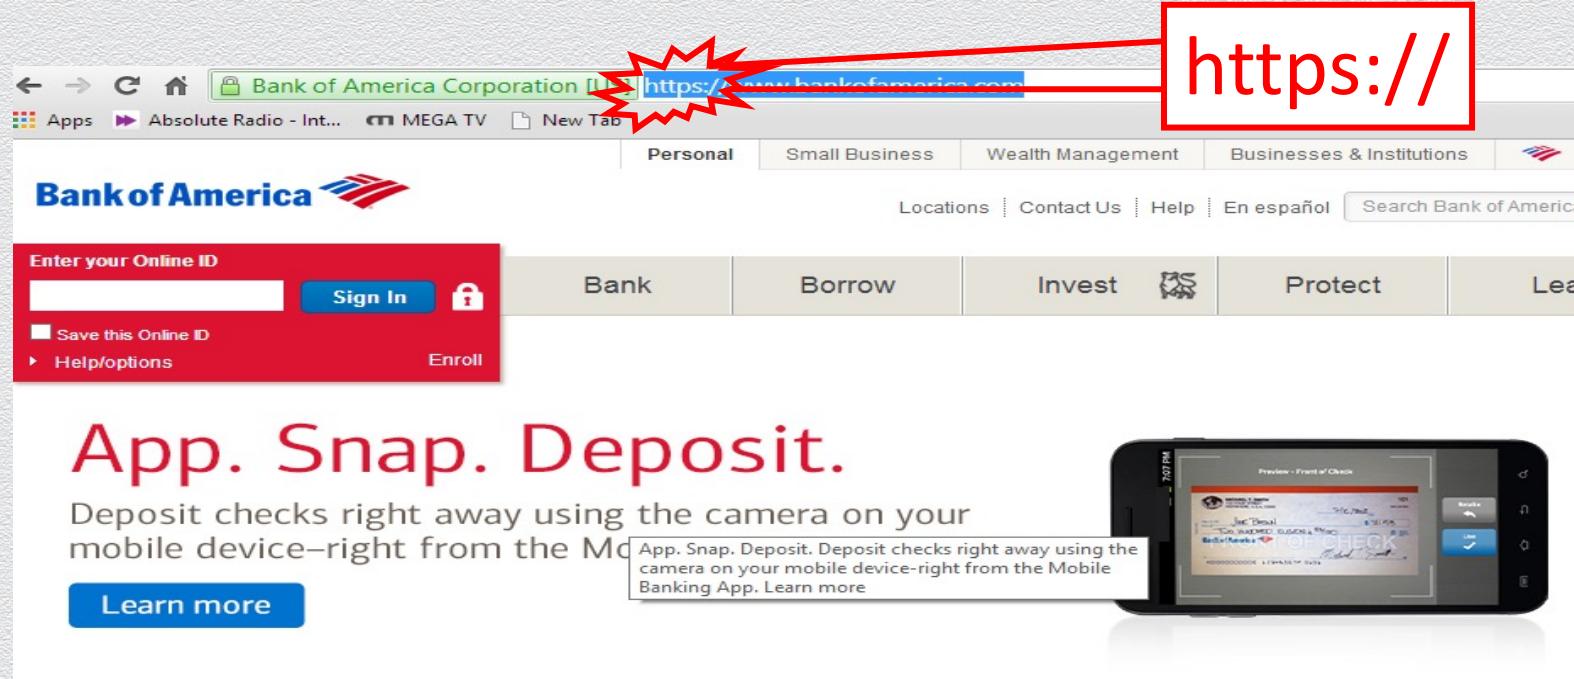

Which is Delwyn's certificate.

## Example 2

What bad things can happen if the root CA system is compromised?

# Secure communication over the Internet

A screenshot of the Bank of America website. A red starburst highlights the `https://` prefix in the browser's address bar. The URL shown is `https://www.bankofamerica.com`. The page features the Bank of America logo and navigation links for Personal, Small Business, Wealth Management, Businesses & Institutions, Locations, Contact Us, Help, En español, and Search Bank of America. A red banner at the top left encourages users to "Enter your Online ID" with fields for "Sign In" and "Enroll". A red call-to-action button says "Learn more" about the "App. Snap. Deposit." service, which allows users to deposit checks right from their mobile device. A smartphone is shown displaying a check image with the text "Preview - Front of Check".

What cryptographic keys are used to protect communication?

## X.509 certificates

Defines framework for authentication services

- ◆ defines that public keys stored as certificates in a public directory
- ◆ certificates are issued and signed by a CA

Used by numerous applications: SSL

Example: see certificates accepted by your browser

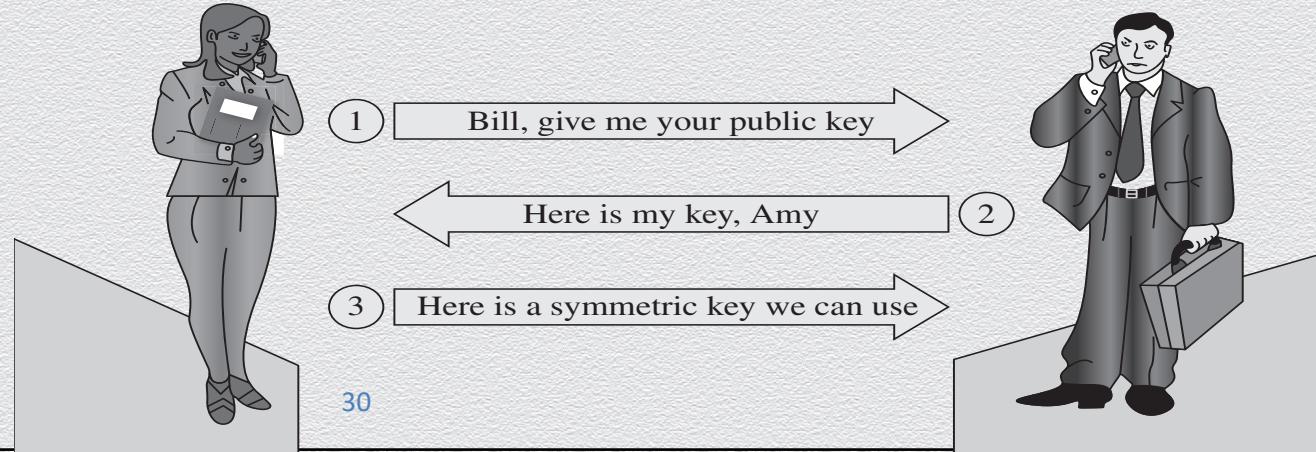

# Hybrid encryption

# Secret-key cryptography is “reduced” to public-key

PK encryption can be used “on-the-fly” to securely distribute session keys

Main idea: Leverage PK encryption to securely distribute session keys

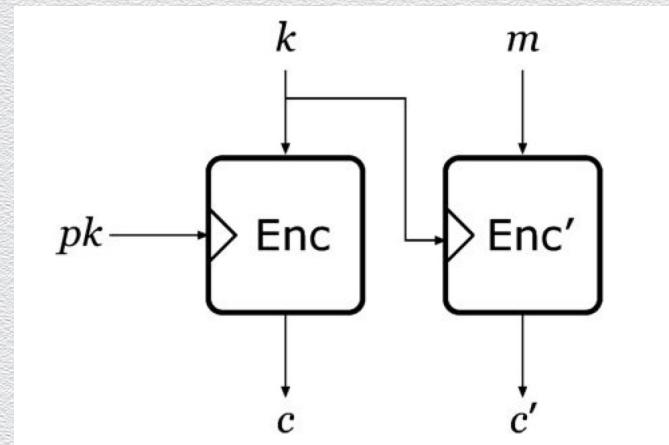

- ◆ sender generates a fresh session-specific secret key  $k$  and **learns** receiver's public key  $R_{pk}$
- ◆ session key  $k$  is sent to receiver encrypted under key  $R_{pk}$
- ◆ session key  $k$  is employed to run symmetric-key crypto
  - ◆ e.g., how **not** to run above protocol

# Hybrid encryption

“Reduces” secret-key crypto to public-key crypto

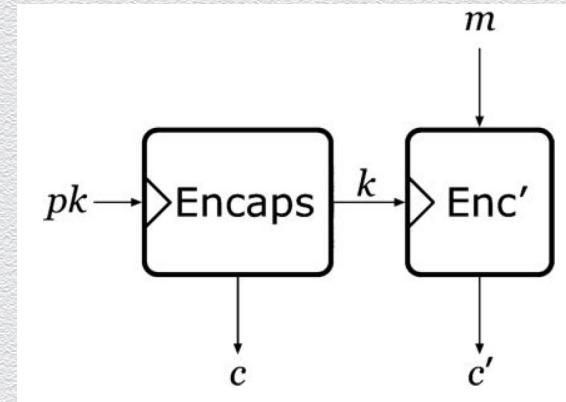

- ◆ better performance than block-based public-key CPA-encryption
- ◆ main idea
  - ◆ apply PK encryption on random key  $k$
  - ◆ use  $k$  for secret-key encryption of  $m$

# Hybrid encryption using the KEM/DEM approach

“Reduces” secret-key crypto to public-key crypto

- ◆ main idea
  - ◆ **encapsulate** secret key  $k$  into  $c$
  - ◆ use  $k$  for secret-key encryption of  $m$
  - ◆ KEM: key-encapsulation mechanism - Encaps
  - ◆ DEM: data encapsulation mechanism - Enc'
- ◆ KEM/DEM scheme
  - ◆ CPA-secure if KEM is CPA-secure and Enc' EAV-secure
  - ◆ CCA-secure if KEM and Enc' are CCA-secure

# The Discrete Log problem & its applications

# The discrete logarithm problem

## Setting

- ◆ if  $p$  be an odd prime, then  $G = (\mathbb{Z}_p^*, \cdot)$  is a cyclic group of order  $p - 1$ 
  - ◆  $\mathbb{Z}_p^* = \{1, 2, 3, \dots, p-1\}$ , generated by some  $g$  in  $\mathbb{Z}_p^*$ 
    - ◆ for  $i = 0, 1, 2, \dots, p-2$ , the process  $g^i \text{ mod } p$  produces all elements in  $\mathbb{Z}_p^*$
    - ◆ for any  $x$  in the group, we have that  $g^k \text{ mod } p = x$ , for some integer  $k$
    - ◆  $k$  is called the **discrete logarithm** (or log) of  $x$  (mod  $p$ )

## Example

- ◆  $(\mathbb{Z}_{17}^*, \cdot)$  is a cyclic group  $G$  with order 16, 3 is the generator of  $G$  and  $3^{16} = 1 \text{ mod } 17$
- ◆ let  $k = 4$ ,  $3^4 = 13 \text{ mod } 17$  (which is easy to compute)
- ◆ the inverse problem: if  $3^k = 13 \text{ mod } 17$ , what is  $k$ ? what about **large  $p$** ?

# Computational assumption

## Discrete-log setting

- ◆ cyclic  $G = (\mathbb{Z}_p^*, \cdot)$  of order  $p - 1$  generated by  $g$ , prime  $p$  of length  $t$  ( $|p|=t$ )

## Problem

- ◆ given  $G, g, p$  and  $x$  in  $\mathbb{Z}_p^*$ , compute the discrete log  $k$  of  $x$  ( $\text{mod } p$ )
- ◆ we know that  $x = g^k \text{ mod } p$  for some unique  $k$  in  $\{0, 1, \dots, p-2\}$ ... but

## Discrete log assumption

- ◆ for groups of specific structure, **solving the discrete log problem is infeasible**
- ◆ any efficient algorithm finds discrete logs negligibly often (prob =  $2^{-t/2}$ )

## Brute force attack

- ◆ cleverly enumerate and **check  $O(2^{t/2})$  solutions**

# ElGamal encryption

Assumes discrete-log setting (cyclic  $G = (Z_p^*, \cdot) = \langle g \rangle$ , prime  $p$ , message space  $Z_p$ )

## Gen

- ◆ secret key: random number  $x \in Z_p^*$       public key:  $A = g^x \text{ mod } p$ , along w/  $G, g, p$

## Enc

- ◆ pick a fresh random  $r \in Z_p^*$  and set  $R = A^r$  ( $= g^{xr}$ )
- ◆ send ciphertext  $\text{Enc}_{PK}(m) = (c_1, c_2)$       where  $c_1 = g^r$ ,  $c_2 = m \cdot R \text{ mod } p$

## Dec

- ◆  $\text{Dec}_{SK}(c_1, c_2) = c_2 (1/c_1^x) \text{ mod } p$       where  $c_1^x = g^{xr}$

Security is based on **Computational Diffie-Hellman** (CDH) assumption

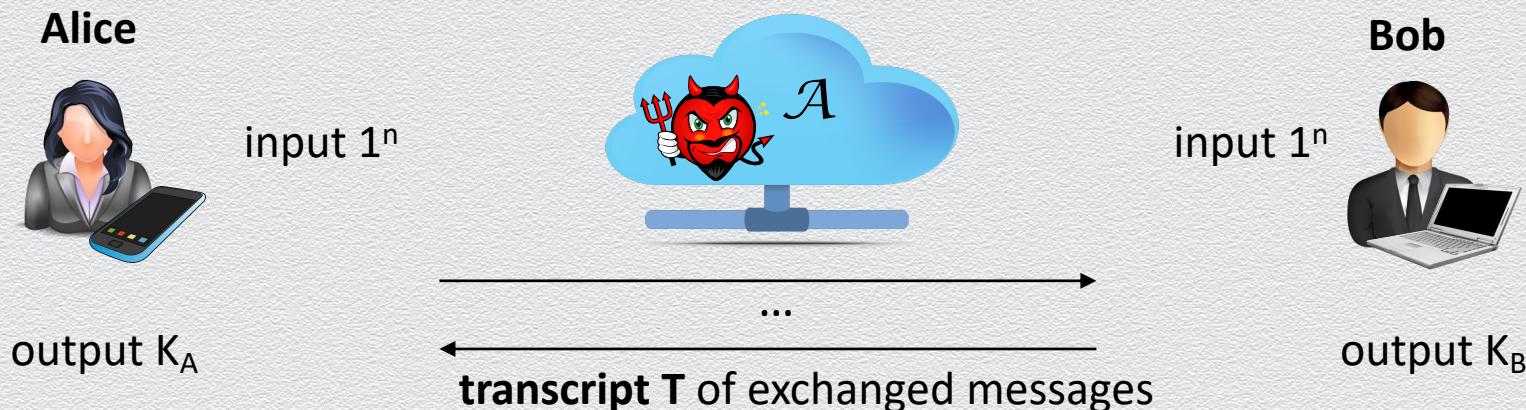

- ◆ given  $(g, g^a, g^b)$  it is hard to compute  $g^{ab}$

A signature scheme can be also derived based on above discussion

# Application: Key-agreement (KA) scheme

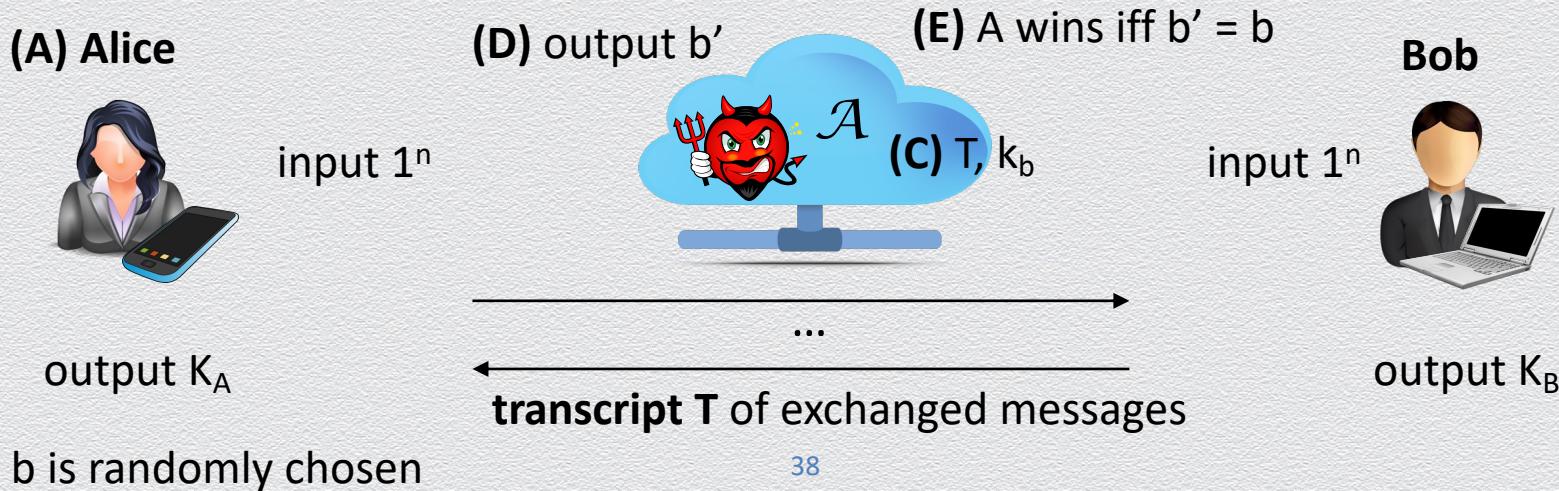

Alice and Bob want to securely establish a **shared key** for secure chatting over an **insecure** line

- ◆ instead of meeting in person in a secret place, they want to use the insecure line...
- ◆ KA scheme: they run a key-agreement protocol  $\Pi$  to contribute to a **shared key K**
- ◆ correctness:  $K_A = K_B$
- ◆ security: no PPT adversary  $\mathcal{A}$ , given  $T$ , can distinguish  $K$  from a truly random one

# Key agreement: Game-based security definition

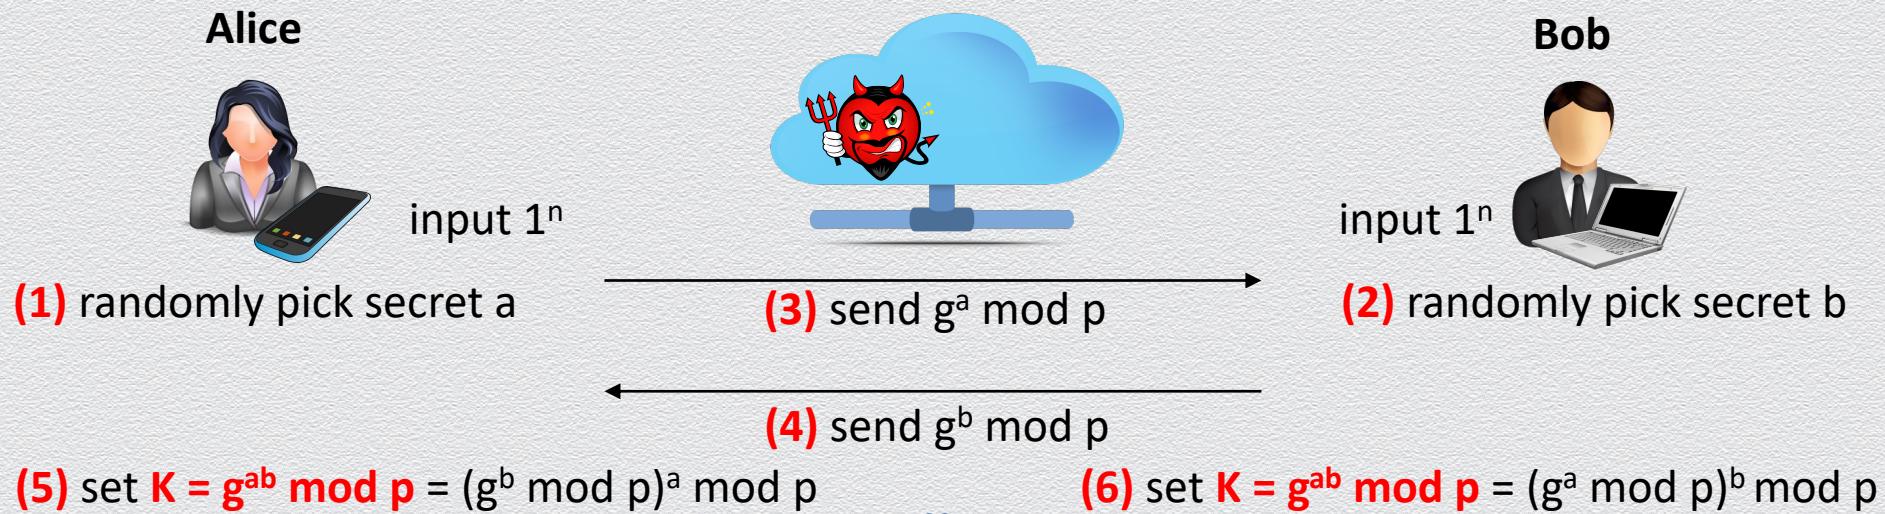

- ◆ scheme  $\Pi(1^n)$  runs to generate  $K = K_A = K_B$  and transcript  $T$ ; random bit  $b$  is chosen
- ◆ adversary  $\mathcal{A}$  is given  $T$  and  $k_b$ ; if  $b = 1$ , then  $k_b = K$ , else  $k_b$  is random (both  $n$ -bit long)
- ◆  $\mathcal{A}$  outputs bit  $b'$  and wins if  $b' = b$
- ◆ then:  **$\Pi$  is secure if no PPT A wins non-negligibly often**

# The Diffie-Hellman key-agreement protocol

Alice and Bob want to securely establish a **shared key** for secure chatting over an **insecure** line

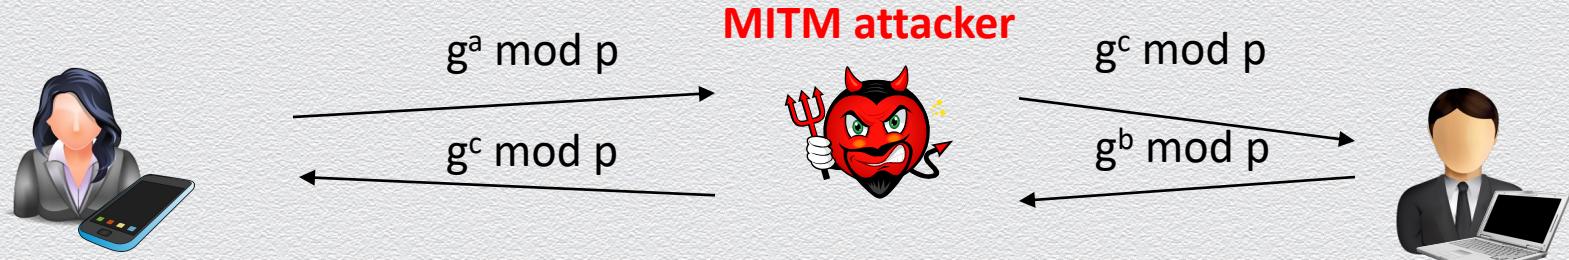

- ◆ DH KA scheme  $\Pi$ 
  - ◆ discrete log setting:  $p, g$  public, where  $\langle g \rangle = Z^*_p$  and  $p$  prime

# Security

- ◆ discrete log assumption is necessary but not sufficient
- ◆ decisional DH assumption
  - ◆ given  $g, g^a$  and  $g^b, g^{ab}$  is computationally indistinguishable from uniform

# Authenticated Diffie-Hellman

Alice computes  $g^{ac} \text{ mod } p$  and Bob computes  $g^{bc} \text{ mod } p$  !!!
